Locking and deadlocks - quick revision

Two-phase locking: a transaction first acquires all its locks in the growing phase and releases them in the shrinking phase. Strict two-phase locking holds exclusive locks until commit.

Two-phase locking can itself lead to deadlocks between transactions. Common deadlock prevention schemes based on timestamps:
- wait-die: an older transaction may wait for a younger one; a younger one requesting a lock held by an older one is rolled back.
- wound-wait: an older transaction wounds (rolls back) the younger one; a younger one waits.

Doubt: do we need this for both the OS paper and the DBMS paper? Check with sir.
